NWTC Library – short overview of subroutines and functions

26-Jul-2012: A. Platt 24-Oct-2012: B. Jonkman

4-Dec-2012: A. Platt (v 1.05.02a) 7-Dec-2012: B. Jonkman (v1.06.00b) 12-Dec-2012: M. Buhl (v1.06.00c)

This documentation was developed for version 1.05.00 of the NWTC Library. Some changes may take place in later versions of the library.

Each file is listed separately with its MODULE and contained subroutines and functions. Unless noted otherwise, the listed routines are subroutines.

SingPrec.f90 (DoublePrec.f90)

Declares kind for single- or double-precision floating-point variables.

MODULE Precision: Stores constants to specify the KIND of variables. This module only contains constants.

NWTC Library.f90

Requires:

ModMesh.f90, NWTC_Aero.f90, NWTC_IO.f90, NWTC_Library.f90, and NWTC Num.f90.

Requires one, but not both, of the following files:

DoubPrec.f90 or SingPrec.f90.

Your project must include one, and only one, of the following files:

SysIVF.f90, SysGnuLinux.f90, SysGunWin.f90, SysIFL.f90, SysMatlab.f90, or SysIVF Labview.f90.

Compilation order for command-line compilation:

SingPrec.f90 (DoubPrec.f90)

SysIVF.f90 (or other Sys*.f90 file)

NWTC IO.f90

NWTC Num.f90

NWTC Aero.f90

ModMesh.f90

NWTC Library.f90

Invoking programs should call NWTC Init() to initialize data important to the use of the library.

MODULE NWTC Library

Name	Arguments	Description
NWTC_Init	ProgNameIn,	Initialize <i>ProgName</i> and <i>ProgVer</i> if
	ProgVerIn	parameters have been passed. This routine
		then calls all required initialization routines.
		Write the version of the NWTC subroutine
		library that we are running

SysIVF.f90 (SysGnuLinux.f90, SysGnuWin.f90, SysIFL.f90, SysMatlab.f90, SysIVF_Labview.f90) Contains routines with system-specific logic and references. It also contains standard (but not system-specific) routines that it uses.

Sys File	Intended Compiler/System
SysIVF.f90	Intel Visual Fortran for Windows compiler
SysIFL.f90	Intel Fortran for Linux compiler
SysGnuLinux.f90	GNU Fortran for Linux compiler
SysGnuWin.f90	GNU Fortran for Linux compiler
SysMatlab.f90	Intel Visual Fortran for Windows compiler with Matlab's mex functions
SysIVF_Labview.f90	Intel Visual Fortran for Windows compiler with references to IFPORT removed
	and no writing to the screen (output to a file named "Console.txt" instead)

MODULE SysSubs:

Name	Arguments	Description
FileSize	FileName,	Calls the routine FSTAT to obtain the size of
	Size	the specify file or returns -1 on error.
FindLine	Str,	Finds one line of text with a maximum length
	MaxLen,	of MaxLen from the Str. It tries to break the
	StrEnd	line at a blank.
FlushOut	Unit	Flushes the buffer on the specified <i>Unit</i> . It is
		especially useful when printing "running"
		type messages.
Get_Arg	Arg_Num,	Gets the Arg_Num'th argument from the
	Arg,	command line.
	Error	Note: The functionality in this routine was replaced by
		GET_COMMAND_ARGUMENT(), which will be available intrinsically in Fortran 2000.
Get_Arg_Num	Arg_Num	Gets the number of command line
		arguments.
		Note: The functionality in this routine was replaced by
		COMMAND_ARGUMENT_COUNT(), which will be available intrinsically in Fortran 2000.
Get CWD	DirName,	Retrieves the path of the current working
_	Status	directory.
Get_Env	EnvVar	Returns the string associated with the EnvVar
(function)		environment variable in the OS. It returns
		the null string of the variable is not found.
		Note: The functionality in this routine was replaced by GET ENVIRONMENT VARIABLE(), which will be
		available intrinsically in Fortran 2000.
Is_NaN	DblNum	Determines if a REAL(DbKi) variable holds
(function)		a proper number.
OpenBinFile	Un,	Opens a binary output file.
	OutFile,	
	RecLen,	
	Error	
OpenBinInpFile	Un,	Opens a binary input file.
	InFile,	
	Error	
OpenCon		Opens the console for standard output.

Name	Arguments	Description
OpenUnfInpBEFile	Un,	Opens a binary input file with data stored in
	InFile,	Big Endian format (created on a UNIX
	RecLen,	machine). Data are stored in RecLen-byte
	Error	records.
ProgExit	StatCode	Stops the program. If the compiler supports
		the EXIT routine, pass the program status to
		it. Otherwise, do a STOP
UsrAlarm		Generates an alarm to warn the user that
		something went wrong.
WrNR	Str	Writes out a string to the screen without
		following it with a new line.
WrOver	Str	Writes out a string that overwrites the
		previous line.
WrScr	Str	Writes out a string to the screen. Break long
		messages into multiple lines.

NWTC_Num.f90

Contains numeric-type routines with non-system-specific logic and references. It also contains global numeric-related variables.

MODULE NWTC_Num:

Name	Arguments	Description
InterpBin	XVal,	Returns a y-value that corresponds to an input x-value by
(function interface)	XAry,	interpolating into the arrays. It returns the first or last YAry() value
	YAry,	if XVal is outside the limits of XAry().
	ILo,	Note: This is an interface for InterpBinComp and InterpBinReal and will call the appropriat one (depending if <i>YAry</i> is complex or real).
T	AryLen	
InterpStp	XVal,	Returns a y-value that corresponds to an input x-value by
(function interface)	XAry,	interpolating into the arrays. It uses the passed index as the starting
	YAry,	point and does a stepwise interpolation from there. This is
	Ind,	especially useful when the calling routines save the value from the
	AryLen	last time this routine was called for a given case where XVal does
		not change much from call to call. When there is no correlation
		from one interpolation to another, InterpBin() may be a better choice. It returns the first or last <i>YAry()</i> value if <i>XVal</i> is outside the
		limits of $XAry()$.
		Note: This is an interface for InterpStpComp and InterpStpReal and will call the appropriate
		one (depending if <i>YAry</i> is complex or real).
AddOrSub2Pi	OldAngle,	This routine is used to convert <i>NewAngle</i> to an angle within 2* <i>Pi</i> or
	NewAngle	OldAngle by adding or subtracting $2*Pi$ accordingly; it then sets
		OldAngle equal to NewAngle. This routine is useful for converting
		angles returned from a call to the ATAN2() FUNCTION into
		angles that may exceed the -Pi to Pi limit of ATAN2(). This
		routine assumes that the angle change between calls is not more
		than 2*Pi in absolute value. <i>OldAngle</i> should be SAVEd in the
DC (D 1	D 14	calling routine.
BSortReal	RealAry,	This routine sorts a list of real numbers. It uses the bubble sort
C D 14	NumPts	algorithm, which is only suitable for short lists.
Cross_Product (function)	Vector1,	This function computes the cross product of two 3-element arrays:
,	Vector2	Cross Product = Vector1 X Vector2 (resulting in a vector).
EqualRealNos (function)	ReNum1, ReNum2	This function compares 2 real numbers and determines if they are
		"almost" equal, <i>i.e.</i> within some relative tolerance.
GetSmllRotAngs (function)	DCMat, ErrStat	This subroutine computes the angles that make up the input direction cosine matrix, <i>DCMat</i> .
GL Pts	IPt,	Returns the non-dimensional (-1:+1) location of the given Gauss-
GL_FIS	NPts,	Legendre Quadrature point and its weight. The values came from
	,	Carnahan, Brice; Luther, H.A.; Wilkes, James O. (1969) "Applied
	Loc, Wt,	Numerical Methods."
	ErrStat	rumorioui mouious.
IndexCharAry	CVal,	Returns an integer index such that $CAry(IndexCharAry) = CVal$
(function)	C V ai, CAry	If no element in the array matches $CVal$, the value -1 is returned
÷ /	CI II y	The routine performs a binary search on the input array to
		determine if <i>CVal</i> is an element of the array; thus, <i>CAry</i> must be
		sorted and stored in increasing alphebetical (ASCII) order. The
		routine does not check that the array is sorted. The routine
		assumes that <i>CVal</i> is type CHARACTER and <i>CAry</i> is an array

Name	Arguments D	escription
LocateBin	XVal,	Finds the lower-bound index of an input x-value located in an
	XAry,	array. On return, Ind has a value such that $XAry(Ind) \le XVal \le$
	Ind,	XAry(Ind+1), with the exceptions that $Ind = 0$ when $XVal < 0$
	AryLen	$XAry(1)$, and $Ind = AryLen$ when $XAry(AryLen) \le XVal$.
	,	Note: If the index doesn't change much between calls, LocateStp() may be a better
T	**** 1	option.
LocateStp	XVal,	Finds the lower-bound index of an input x-value located in an
	XAry,	array. On return, <i>Ind</i> has a value such that <i>XAry(Ind)</i> <= <i>XVal</i> <
	Ind,	XAry(Ind+1), with the exceptions that $Ind = 0$ when $XVal < 0$
	AryLen	$XAry(1)$, and $Ind = AryLen$ when $XAry(AryLen) \le XVal$.
		It uses the passed index as the starting point and does a stepwise
		search from there. This is especially useful when the calling
		routines save the value from the last time this routine was called
		for a given case where XVal does not change much from call to
		call. When there is no correlation from one interpolation to
		another, a binary search may be a better choice.
Mean	Ary,	Function to calculate the mean value of a vector array.
(function)	AryLen	
MPi2Pi	Angle	Ensures that <i>Angle</i> lies between <i>-Pi</i> and <i>Pi</i> .
SetConstants		Computes some useful constants based upon <i>Pi</i> and IEEE
		arithmetic.
RombergInt	f,	Used to integrate a function f over the interval $[a, b]$ (f is an
C	a, b,	external function). This routine is useful for sufficiently smooth
	R,	(e.g., analytic) integrands, integrated over intervals which
	err, eps,	contain no singularities, and where the endpoints are also
	ErrStat	nonsingular.
SmllRotTrans	RotationType,	This routine computes the 3x3 transformation matrix, <i>TransMat</i> ,
	Theta1,	to a coordinate system x (with orthogonal axes x_1, x_2, x_3)
	Theta2,	resulting from three rotations (<i>Theta1</i> , <i>Theta2</i> , <i>Theta3</i>) about the
	Theta3,	orthogonal axes (X_1, X_2, X_3) of coordinate system X. All angles
	TransMat,	are assumed to be small, as such, the order of rotations does not
	ErrTxt	matter and Euler angles do not need to be used. This routine is
	Liiin	used to compute the transformation matrix (<i>TransMat</i>) between
		undeflected (X) and deflected (x) coordinate systems.
		See the subroutine in the file NWTC Num.f90 for more details.
SortUnion	Ary1, N1,	
SortUnion		Takes two sorted arrays and finds the sorted union of the two. Note: If the same value is found in both arrays, only one is kept. However, if either
	Ary2, N2,	array as multiple occurrences of the same value, the largest multiple will be kept.
~ 15 T	Ary, N	Duplicates should be eliminated externally if this is not desirable
StdDevFn	Ary,	Calculates the standard deviation of a population contained in
(function)	AryLen,	Ary.
	Mean	

NWTC_IO.f90

Contains I/O-related variables and routines with non-system-specific logic.

MODULE NWTC_IO:

AdjRealStr (Minerface) Aury (merface) Ary (merfac	Name	Arguments	Description

CloseEcho Conv2UC Str Converts all the text in Str to upper case. CountWords (function) Line Function that counts the number of "words" in a line of text. It uses spaces, tabs, commas, semicolons, single quotes, and double quotes ("whitespace") as word separators. CurDate (function) CurTime (function) CurTime (function) Function that returns a character string encoded with the date in the form dd-mmm-ccyy. CurTime (function) ProgDesc, Name/Ver Amme/Ver Function that returns a character string encoded with the time in the form "hh:mm:ss". DispNVD Cinterface) ProgDesc, Name/Ver Note: This interface will call the appropriate allocation subroutine depending on the type and number of arguments passed. This interfaces to: DispNVDD - no inputs. The global variables ProgName and ProgVer are used DispNVD1 - Single input of type ProgDesc. DispNVD2 - Two arguments of character type containing the name and version info FIt2LStr (function) GetNewUnit UnIn Returns a unit number not currently in use. GetNVD ProgDesc Returns a string with the program name, version, and date (converts data structure to single string) GetPath GivenFil, PathName Converts data structure to single string) GetRoot GivenFil, PathName Converts data structure to single string) GetRoot Returns a string with the program name of the given file. It counts everything before (and including) the last "\" or "\" Parses the root file name from the name of the given file. It counts everything after the last period as the extension. GetTokens Line, NumTok, Tokens, Error GetWords Line, Retrieves NumWords "words" from a Line of text.	CHCCKIOS		•
CloseEcho Closes the echo file and sets <i>Echo</i> to false. Conv2UC Str Converts all the text in <i>Str</i> to upper case. CountWords Line Function that counts the number of "words" in a line of text. It uses spaces, tabs, commas, semicolons, single quotes, and double quotes ("whitespace") as word separators. CurDate (function) dd-mmm-ccyy. CurTime (function) Function that returns a character string encoded with the date in the form dd-mmm-ccyy. DispNVD			invalid input message, and then about the program.
CloseEcho Closes the echo file and sets Echo to false.			
Conv2UC Str Converts all the text in Str to upper case.	CloseEcho		Closes the echo file and sets <i>Echo</i> to false.
CountWords (function) Line (function) CurDate (function) CurDate (function) CurTime (function) CurTime (function) DispNVD (interface) ProgDesc, Name/Ver Flunction that returns a character string encoded with the time in the form "hh:mm:ss". DispNVDand in interface will call the appropriate allocation subroutine depending on the type and number of arguments passed. This interfaces to: - DispNVD2 - DispNVD2 - DispNVD3 - DispNVD3 - DispNVD4 - DispNVD3 - DispNVD4 - DispNVD4 - DispNVD4 - DispNVD4 - DispNVD5 - DispNVD5 - DispNVD6	Conv2UC	Str	Converts all the text in <i>Str</i> to upper case.
Uses spaces, tabs, commas, semicolons, single quotes, and double quotes ("whitespace") as word separators. CurDate (function)		Line	Function that counts the number of "words" in a line of text. It
CurDate (function) dd-mmm-ccyy. CurTime (function) Function that a character string encoded with the date in the form dd-mmm-ccyy. CurTime (function) Function that returns a character string encoded with the time in the form "hh:mm:ss". DispNVD Displays the name of the program, its version, and its release date. Name/Ver Note: This interface will call the appropriate allocation subroutine depending on the type and number of arguments passed. This interfaces to: - DispNVD0 - no inputs. The global variables ProgName and ProgVer are used - DispNVD0 - no inputs. The global variables ProgName and ProgVer are used - DispNVD0 - no inputs. The global variables ProgName and ProgVer are used - DispNVD0 - No inputs. The global variables ProgName and ProgVer are used - DispNVD0 - Two arguments of character type containing the name and version info Flt2LStr (function) GetNewUnit UnIn Returns a unit number not currently in use. GetNVD (function) GetNot GivenFil, Parses the path name from the name, version, and date (converts data structure to single string) GetPath GivenFil, Parses the path name from the name of the given file. It counts everything before (and including) the last "\" or "\". GetRoot GivenFil, Parses the root file name from the name of the given file. It counts everything after the last period as the extension. GetTokens Line, Parses Line for NumTok "tokens" and return them in the Tokens array. This routine differs from GetWords() in that it uses only spaces as token separators. Error GetWords Line, Retrieves NumWords "words" from a Line of text.	(function)		
CurDate (function) CurTime (function) CurTime (function) Function that a character string encoded with the date in the form dd-mmm-ccyy. Function that returns a character string encoded with the time in the form "hh:mm:ss". DispNVD (interface) ProgDesc, Name/Ver Note: This interface will call the appropriate allocation subroutine depending on the type and number of arguments passed. This interfaces to: - DispNVD0 - no inputs. The global variables ProgName and ProgVer are used - DispNVD1 - Single input of type ProgDesc DispNVD2 - Two arguments of character type containing the name and version info Flt2LStr (function) GetNewUnit UnIn Returns a unit number not currently in use. GetNVD (function) GetNewUnit GetNewInit GivenFil, Parses the path name from the name of the given file. It counts everything before (and including) the last "\" or "/". GetRoot GivenFil, Parses the root file name from the name of the given file. It counts everything after the last period as the extension. GetTokens Line, Parses Line for NumTok "tokens" and return them in the Tokens array. This routine differs from GetWords() in that it uses only spaces as token separators. Error GetWords Line, Retrieves NumWords "words" from a Line of text. Words,			*
CurTime (function) DispNVD (interface) ProgDesc, Name/Ver Anti- DispNVD (interface) ProgDesc, Name/Ver Displays the name of the program, its version, and its release date. Note: This interface will call the appropriate allocation subroutine depending on the type and number of arguments passed. This interfaces to: - DispNVD0 - no inputs. It counts everything after the last period as the extension.GetTokensLine, NumTok, Tokens, ErrorParses Line for NumTok "tokens" and return them in the Tokens array. This routine differs from GetWords() in that it uses only spaces as token separators.GetWordsLine, Words,Retrieves NumWords "words" from a Line of text.	•	UnIn	Returns a unit number not currently in use.
GetPath GivenFil, Parses the path name from the name of the given file. It counts everything before (and including) the last "\" or "/". GetRoot GivenFil, RootName Counts everything after the last period as the extension. GetTokens Line, NumTok, Tokens, Error GetWords Line, Retrieves NumWords "words" from a Line of text. Words, Converts data structure to single string) Parses the path name from the name of the given file. It counts everything after the last period as the extension. Parses Line for NumTok "tokens" and return them in the Tokens array. This routine differs from GetWords() in that it uses only spaces as token separators. Error GetWords Line, Retrieves NumWords "words" from a Line of text. Words,	GetNVD	ProgDesc	
GetPath GivenFil, PathName everything before (and including) the last "\" or "/". GetRoot GivenFil, RootName Counts everything after the last period as the extension. GetTokens Line, NumTok, Tokens, Error GetWords Line, Retrieves NumWords "words" from a Line of text. Words, Parses the path name from the name of the given file. It counts everything after the last period as the extension. Parses Line for NumTok "tokens" and return them in the Tokens array. This routine differs from GetWords() in that it uses only spaces as token separators. Error GetWords Line, Retrieves NumWords "words" from a Line of text. Words,	(function)	C	
PathName everything before (and including) the last "\" or "/". GetRoot GivenFil, Parses the root file name from the name of the given file. It counts everything after the last period as the extension. GetTokens Line, Parses Line for NumTok "tokens" and return them in the Tokens NumTok, array. This routine differs from GetWords() in that it uses only spaces as token separators. Error GetWords Line, Retrieves NumWords "words" from a Line of text. Words,	GetPath	GivenFil,	· · ·
GetRoot GivenFil, RootName Counts everything after the last period as the extension. GetTokens Line, NumTok, Tokens, Error GetWords Line, Retrieves NumWords "words" from a Line of text. Words, Parses the root file name from the name of the given file. It counts everything after the last period as the extension. Parses Line for NumTok "tokens" and return them in the Tokens array. This routine differs from GetWords() in that it uses only spaces as token separators. Error GetWords Line, Retrieves NumWords "words" from a Line of text. Words,			
RootName counts everything after the last period as the extension. GetTokens Line, Parses Line for NumTok "tokens" and return them in the Tokens NumTok, array. This routine differs from GetWords() in that it uses only spaces as token separators. Error GetWords Line, Retrieves NumWords "words" from a Line of text. Words,	GetRoot	GivenFil,	• • •
GetTokens Line, Parses Line for NumTok "tokens" and return them in the Tokens NumTok, array. This routine differs from GetWords() in that it uses only spaces as token separators. Error GetWords Line, Retrieves NumWords "words" from a Line of text. Words,		RootName	
Tokens, spaces as token separators. Error GetWords Line, Retrieves NumWords "words" from a Line of text. Words,	GetTokens	Line,	• • • •
Tokens, spaces as token separators. Error GetWords Line, Retrieves NumWords "words" from a Line of text. Words,			
GetWords Line, Retrieves NumWords "words" from a Line of text. Words,		Tokens,	•
Words,			
Words,	GetWords	Line,	Retrieves <i>NumWords</i> "words" from a <i>Line</i> of text.
NumWords		Words,	
		NumWords	

Name	Arguments	Description
NameOFile	InArg,	Get the name of the input file from the <i>InArg</i> th command-line
	OutExten,	argument. Remove the extension if there is one, and append
	OutFile,	OutExten to the end.
	ErrStat	
NormStop		Performs a normal termination of the program.
Num2LStr	Num	Converts a floating point number to a left-aligned string. It
(function interface)		eliminates trailing zeroes and the decimal point on floating point
		numbers.
		Note: This is an interface to several the functions Int2LStr, R2LStr4, R2LStr8, and R2LStr16. It will call the appropriate one depending on the type of <i>Num</i> .
OpenBin	Un,	Opens a binary output file.
1	OutFile,	
	RecLen,	
	ErrStat	
OpenBInpFile	Un,	Opens a binary input file.
	InFile,	
	ErrStat	
OpenEcho	Un,	Opens a formatted output file for the echo file.
	OutFile,	
	ErrStat	
OpenFInpFile	Un,	Opens a formatted input file.
	InFile,	
	ErrStat	
OpenFOutFile	Un,	Opens a formatted output file.
	OutFile,	
	ErrStat	
OpenFUnkFile	Un,	Opens a formatted output file and returns a flag (Exists) telling if
	OutFile,	it already existed.
	FailAbt,	
	Failed,	
	Exists,	
O.,I.II., DEE:1.	ErrStat	O
OpenUInBEFile	Un,	Opens an unformatted input file of <i>RecLen</i> -byte data records
	InFile,	stored in Big Endian format.
	RecLen, ErrStat	
OpenUInfile	Un,	Opens an unformatted input file.
оренонине	InFile,	opens an amornatica input me.
	ErrStat	
OpenUOutfile	Un,	Opens an unformatted output file.
· p · · · · · · · · · · · · · · · · · ·	OutFile,	· P · · · · · · · · · · · · · · · · · ·
	ErrStat	
PathIsRelative	GivenFil	Determine if the given file name is absolute or relative. A path is
(function)		considered an absolute path one that satisfies one of the
		following criteria:
		1) It contains ":/" or ":\"
		2) It starts with "/" or "\"
		All others are considered relative.

Name	Arguments	Description
PremEOF	Fil,	Write out an EOF message and aborts the program.
	Variable,	
D 41 :	TrapErrors	
ProgAbort	Message,	Outputs fatal error messages and stops the program.
D D	TrapErrors	D d l l d l D
ProgPause		Pauses the program and requires the user enter an <enter> to</enter>
D 111	3.4	resume execution.
ProgWarn	Message	Outputs non-fatal warning <i>Message</i> and returns to the calling routine.
ReadAry	UnIn, Fil,	Reads in <i>AryLen</i> values into the array <i>Ary</i> from the next <i>AryLen</i>
(interface)	Ary,	lines of the input file.
, ,	AryLen,	Note: This is an interface to the subroutines ReadCAry, ReadIAry, ReadLAry, and
	AryName,	ReadRAry. It will call the appropriate one depending on the type of <i>Ary</i> .
	AryDescr,	ReadRAry can read values separated by white space from the same line of the input file as well.
	ErrStat	
ReadAryLines	UnIn, Fil,	Reads in <i>AryLen</i> values into the array <i>Ary</i> from the next <i>AryLen</i>
(interface)	Ary, AryLen,	lines of the input file.
,	AryName,	Note: This is an interface to the subroutines ReadCAryLines, ReadDAryLines, and
	AryDescr,	ReadRAry. It will call the appropriate one depending on the type of <i>Ary</i> .
	ErrStat	
ReadCom	UnIn,	Reads a comment from the next line of the input file.
110000000111	Fil,	Trouble w Committee from the none may be an imput me.
	ComName,	
	ErrStat	
ReadFASTBin	UnIn,	Reads the contents of a FAST binary output file and stores it in
	FASTdata,	FASTdata. The name of the data file is input through the
	ErrLev,	FASTdata structure by the calling procedure.
	ErrMsg	5
ReadNum	UnIn,	Reads a single word from a file and tests to see if it's a pure
	Fil,	number (no true or false).
	Word,	(
	VarName,	
	ErrStat	
ReadOutputList	UnIn,	Reads a <i>AryLen</i> values into a real array from the next <i>AryLen</i>
	Fil,	lines of the input file.
	CharAry,	
	AryLenRead,	
	•	
	AryName.	
	AryName, AryDescr,	
	AryDescr,	
ReadStr	AryDescr, ErrStat	Reads a string from the next line of the input file.
ReadStr	AryDescr, ErrStat UnIn,	Reads a string from the next line of the input file.
ReadStr	AryDescr, ErrStat UnIn, Fil,	Reads a string from the next line of the input file.
ReadStr	AryDescr, ErrStat UnIn, Fil, CharVar,	Reads a string from the next line of the input file.
ReadStr	AryDescr, ErrStat UnIn, Fil,	Reads a string from the next line of the input file.

Name	Arguments	Description
ReadVar	UnIn, Fil,	Reads in variable <i>Var</i> from the next line of the input file. <i>Var</i>
(interface)	Var,	can be of type CHARACTER, DOUBLE, INTEGER,
	VarName,	LOGICAL, or REAL.
	VarDescr,	Note: This is an interface to the subroutines ReadCVar, ReadDVar, ReadIVar, ReadLVar,
	ErrStat	and <i>ReadRVar</i> . It will call the appropriate one depending on the type of <i>Var</i> .
WaitTime	WaitSecs	Waits for WaitSecs before proceeding.
WrFileNR	Unit,	Writes out the string, Str, to the file connected to Unit without
	Str	following it with a new line.
WrML	Str	Writes out the string, <i>Str</i> , in the middle of a line.
WrPr	Str	Writes out a prompt with text Str to the screen without following
		it with a new line, though a new line precedes it.
WrScr1	Str	Writes out the string, <i>Str</i> , to the screen after a blank line.

NWTC Aero.f90

This module contains aerodynamics routines with non-system-specific logic and references. It also contains global aerodynamics-related variables.

MODULE NWTC Aero:

Name	Arguments	Description
AeroInt	ISeg, Alpha, Re, AF_Table, IntData, DoCl, DoCd, DoCm, DoCpmin, ErrStat	Finds the Re-bounding tables and then calls GetCoef() to get the desired coefficients for the two tables and then interpolates between them.
CompDR	NumSeg, RLoc, HubRad, RotorRad, DimenInp, DelRLoc, ErrStat	Computes the segment lengths from the local radii and the rotor radius. It prints and error if the list of radii is not realizable.
GetAF	AF_File, AF_Table, ISeg	Get airfoil data from either a new NWTC-style or an old AeroDyn-style airfoil file.
GetCoef (function)	ISeg, Alpha, AlfaTab, CoefTab, NumRows, Ind, ErrStat	Interpolation routine for airfoil section coefficients.
GetCoefs	ISeg, Alpha, Re, AF_Table, ClInt, CdInt, CmInt, CpminInt, DoCl, DoCd, DoCm, DoCpmin, ErrStat	Finds the Re-bounding tables and then calls GetCoef() to get the desired coefficients for the two tables and then interpolates between them.
